2. Understanding Section

During the first four lessons of Vue Mastery, I learned the basic concepts of Vue 3 and how to build a simple reactive web application. First, I created a Vue app using Vue.createApp() and mounted it to an HTML element with app.mount('#app'). This helped me understand how Vue connects JavaScript logic with the HTML structure. I also defined reactive data properties such as product, description, image and production's status inside the data() function, which allowed Vue to manage the application's state.

I learned how to dynamically link an image URL using attribute binding with the v-bind directive. Instead of hardcoding the image source in HTML, I connected it to Vue data so that the image could change automatically when the data changed. I also studied how to use conditional rendering with v-if and v-else to control what content is displayed on the screen based on certain conditions, such as product availability.

Through these lessons, I understood how Vue's reactivity system works, how data binding connects JavaScript and HTML and how conditional logic can be applied in the user interface. These concepts are essential for developing interactive and dynamic front-end applications. They provide a strong foundation for building more complex Vue projects in the future.
